The nature of focal attention: Unitary or divided?

Single, unitary focus:

Ericksen & Yeh, 1985
Barriopedro & Botella, 2002;
Jonides, 1983
Benso et al., 1992

Divided, dual foci:

Müller et al., 2003
Kawahara & Yamada, 2006
Yamada & Kawahara, 2007
Adamo, Pun, & Pratt, 2008

The nature of focal attention: Unitary or divided?

Can either mode be employed, depending on task demands?

Is it possible to morph from one mode to the other during a task?

How long does the morphing take?

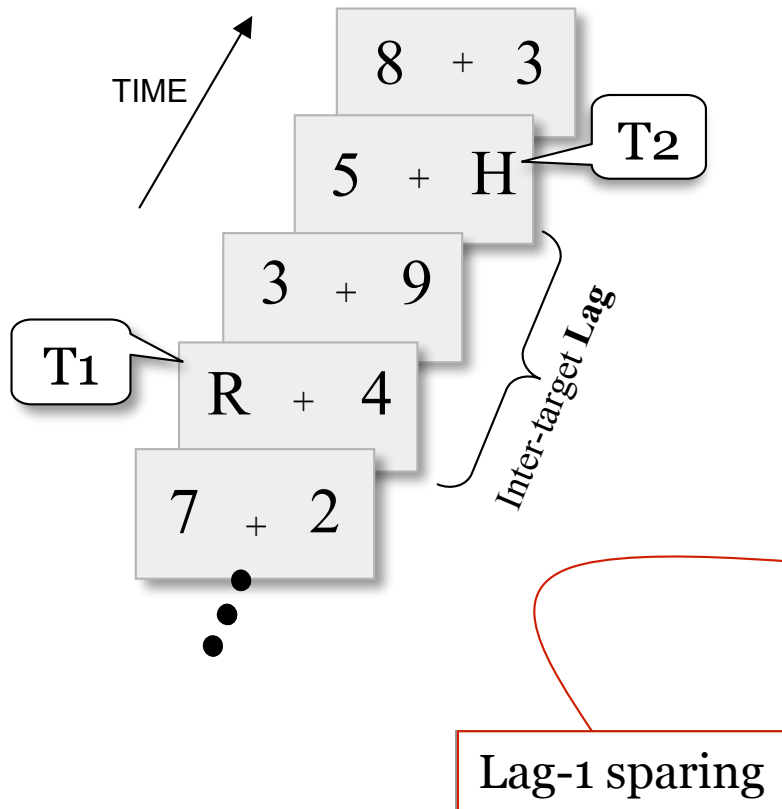

Is there a default mode of attentional deployment?

The Attentional Blink (AB)

“K” and “N”

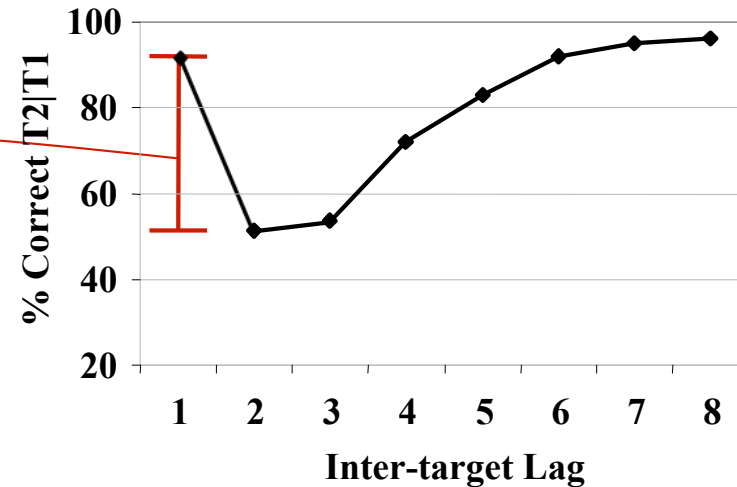

The Attentional Blink (AB)

Lag-1 sparing only occurs if T2 falls within the focus of attention.

Hence, we can use the incidence of Lag-1 sparing to probe whether a spatial location falls within the focus of attention or not.

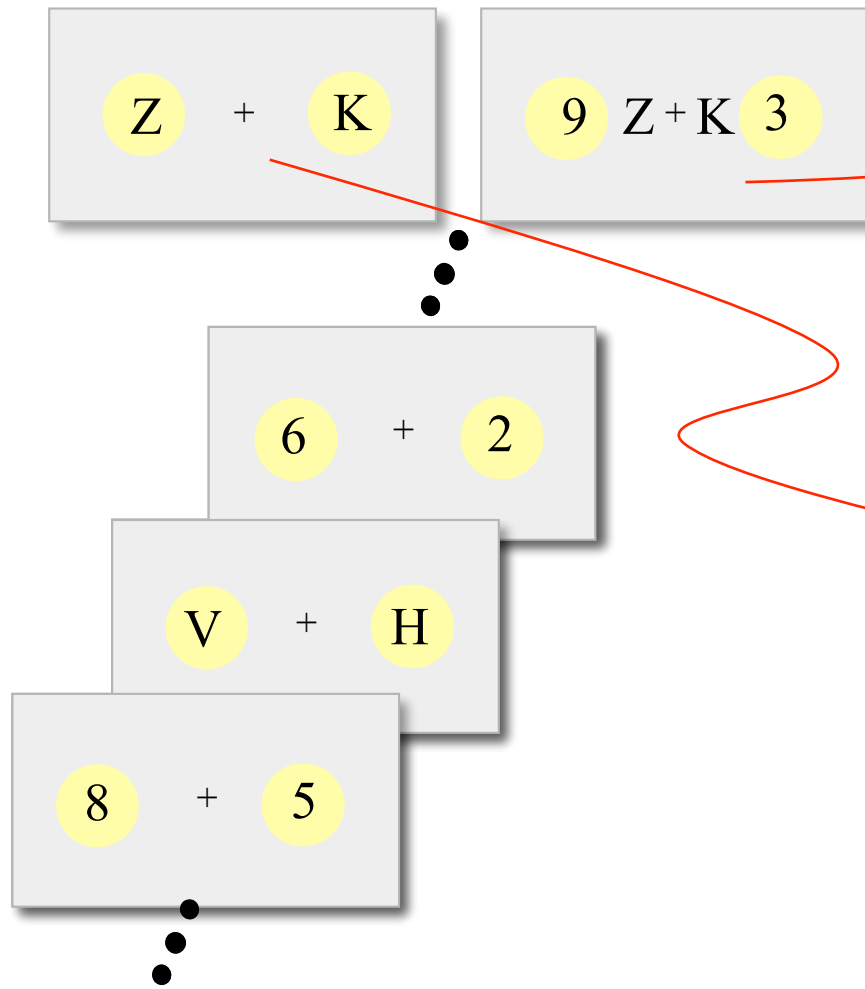

The Attentional Blink (AB)

Our paradigm:

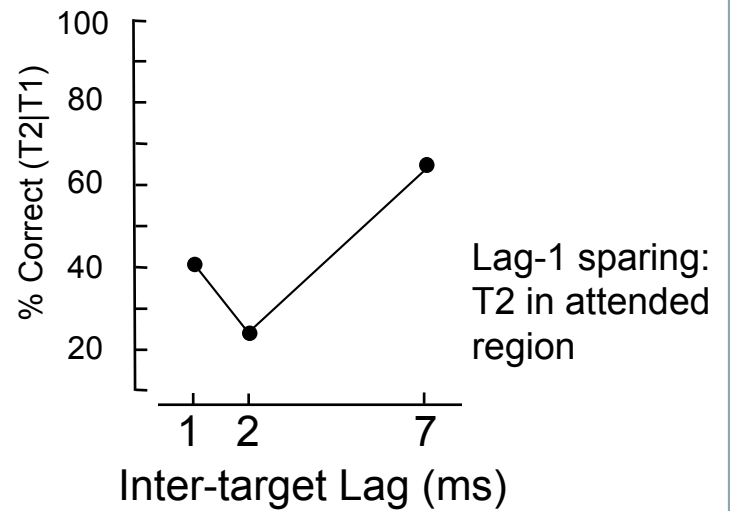

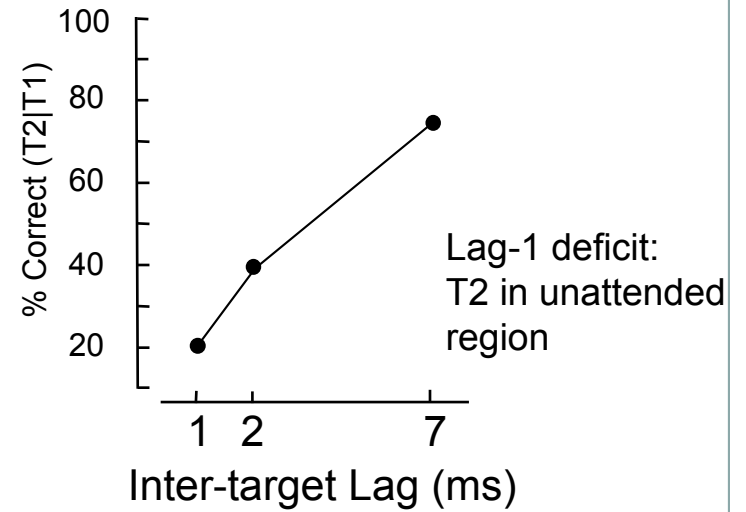

T1-pair always in-stream

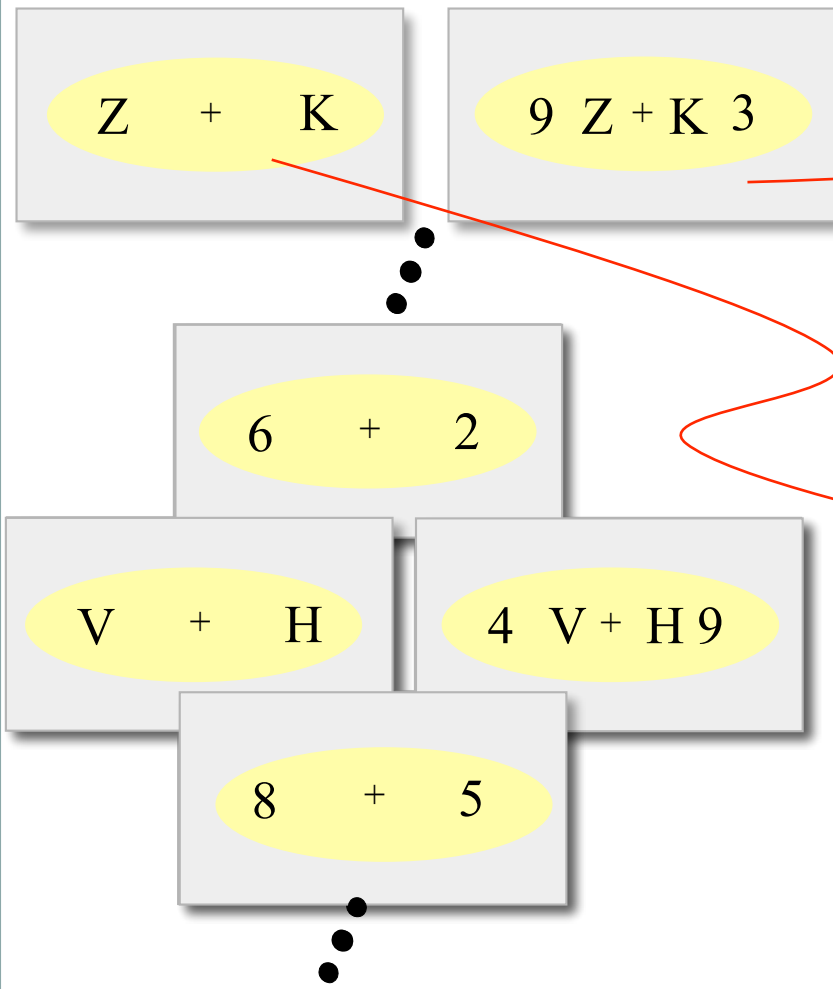

Divided, dual-foci mode

Predictions:

T1-pair unpredictable
Unitary, single-focus

Predictions:

T1-pair always in-stream

Divided mode

T1-pair unpredictable

Unitary mode

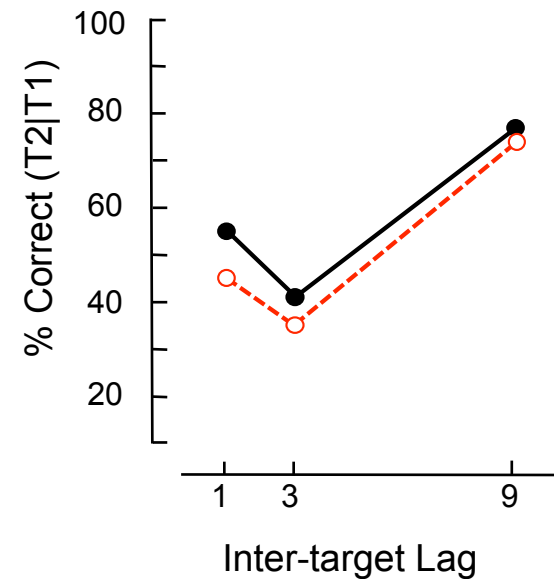

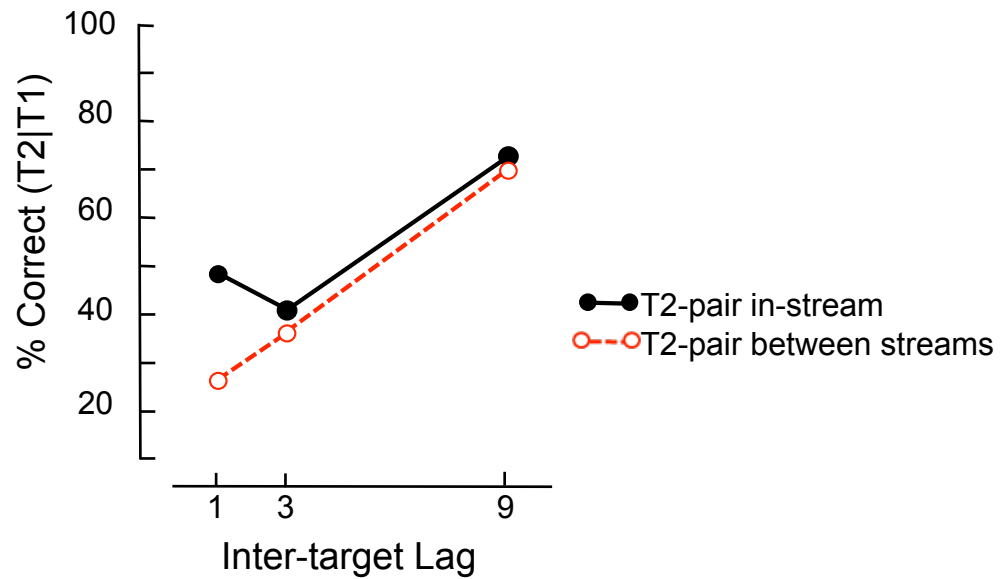

T1-pair always in-stream

Divided mode

T1-pair unpredictable

Unitary mode

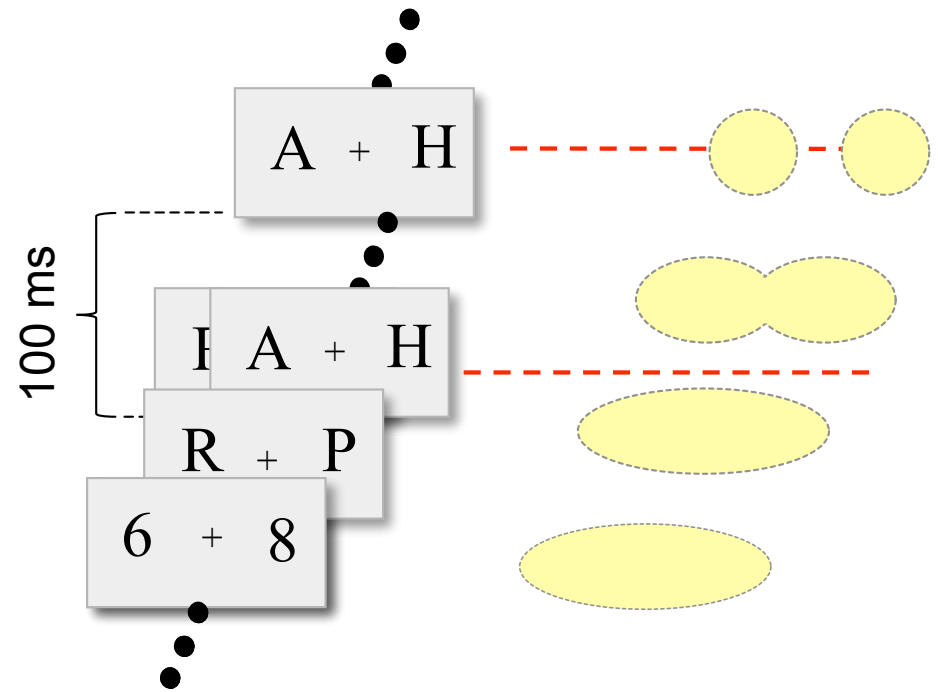

T1-pair always in-stream

Divided mode

What if the focus of attention is initially unitary, but divides over time?

SOA = 70 ms

At 70 ms SOA, attention may already be divided

T1-pair always in-stream

Divided mode

T1-pair unpredictable

Unitary mode

SOA = 70 ms

SOA = 100 ms

SOA = 70 ms

SOA = 100 ms

Thank you!

Whether a unitary or a divided focus is employed depends on *task demands*.

The focus of attention can morph from unitary to divided within 100 ms.

The “default” mode may be unitary.
